

Virtual Machine — imaginary computer/machine that we can write code for, but is ultimately simulated on some underlying machine.

Turing — Universal Turing machine — can simulate any other.

- Java Virtual Machine
- Microsoft .NET CLI
Common lang. interface — C#, F#, ...

- LLVM
(low-level virtual machine)

- Wine
- WSL
- VirtualBox, VMware
- Docker

Hack Virtual Machine.

- Stack machine — everything centers around a stack.
- Arithmetic, logic, etc. operations on stack.
 - Saving/loading from memory always to/from stack.
 - Functions are saved on stack.

Commands

- Arith., logic + comparison } Proj. 7, today + Thurs.
- Memory access ← }
- Branching }
- Function calls }

Stack Arithmetic

$$x + y \rightarrow \begin{array}{l} \text{push } x \\ \text{push } y \\ \text{add} \end{array} \rightarrow \underline{x} \rightarrow \underline{\frac{y}{x}} \rightarrow \underline{\frac{x+y}{x}}$$

$$(x + y) * z \rightarrow \begin{array}{l} \text{push } x \\ \text{push } y \\ \text{add} \\ \text{push } z \\ \text{mul} \end{array} \rightarrow \underline{x} \rightarrow \underline{\frac{y}{x}} \rightarrow \underline{\frac{x+y}{x}} \rightarrow \underline{\frac{z}{x+y}}$$

$$x - (y * z) \rightarrow \begin{array}{l} \text{push } x \\ \text{push } y \\ \text{push } z \\ \text{mul} \\ \text{sub} \end{array} \rightarrow \underline{\frac{y}{x}} \rightarrow \underline{\frac{y * z}{x}} \rightarrow \underline{\frac{x - (y * z)}{x}}$$

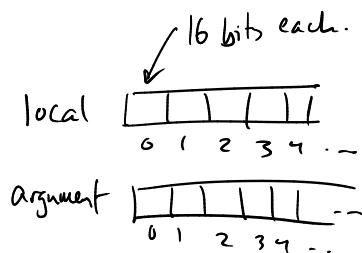

Can always push in order $L \rightarrow R$ — only question is when to do the operations.

$$x + 3 * f(9 - y, g(x)) \rightarrow \underline{x} \rightarrow \underline{\frac{3}{x}} \rightarrow \underline{\frac{9}{\frac{3}{x}}} \rightarrow \underline{\frac{9}{\frac{3}{x}}}$$

↙
 push x ↙
 push 3 $\frac{9-y}{3}$ $\frac{x}{9-y}$ $\frac{g(x)}{3}$
 push 9 $\frac{3}{x}$ $\frac{3}{x}$ $9-y$
 push y $\underline{\frac{x}{x}}$ $\underline{\frac{3}{x}}$ $\underline{\frac{3}{x}}$
 sub $\underline{\frac{9-y}{x}}$ $\underline{\frac{9-y}{x}}$ $\underline{\frac{3}{x}}$
 ↗
 push x ↗
 call g $f(9-y, g(x))$ \dots
 call f $\underline{\frac{3}{x}}$
 mul $\underline{\frac{3}{x}}$
 add

Hack VM memory

- Memory consists of a collection of segments. e.g.
 - Every push or pop operates to/from a particular segment.
 - push <segment> <index>. e.g. push local 2. = read from index 2 of local seg. + push onto stack.
 - Pop <segment> <index>.

Segments

- Constant — push-only, push constant 3 = push value 3.
- Argument — holds arguments passed to current function.
- Local — holds local variables of current function.
- Temp — temporary storage.
- Static — storage for static (i.e. global) vars.

this, that, pointer — next week.

High-level	VM code	Argument	local
<pre>def f(x, y): z = x + 2 p = (z > 3) and (y < x) return p.</pre>	<pre>// x + 2 push argument 0 push constant 2 add // z = ... pop local 0 // z > 3 push local 0 push constant 3 gt // y < x push argument 1 push argument 0 lt and pop local 1 // p = ... push local 1 return</pre>	<pre>0 1</pre> <p>(x) (y)</p>	<pre>0 1</pre> <p>(z) (p)</p>

Translating VM Code → Assembly?

1. push constant 3.

④ 3

D=A

④ SP

A=M

M=D

④ SP

M=M+1

④ SP = stack pointer = address of top of stack — address of first empty mem. loc. above the stack.
